

CVE-2025-4318 - Input validation issue in AWS Amplify Studio UI component properties

Publication Date: 2025/05/05 11:00 AM PDT

Description

The AWS Amplify Studio `amplify-codegen-ui` is an AWS package that generates front-end code from UI Builder entities (components, forms, views, and themes), primarily used in Amplify Studio for component previews and in AWS Command Line Interface (AWS CLI) for generating component files in customers' local applications.

We identified CVE-2025-4318, an input validation issue in Amplify Studio UI component properties. When importing a component schema using the `create-component` command, Amplify Studio will import and generate the component on the users' behalf. The expression-binding function does not validate the component schema properties before converting them to expressions. As a result, an authenticated user who can create or modify components could run arbitrary JavaScript code during the component rendering and build process.

We released a fix in 2.20.3 and recommend users upgrade to address this issue. Additionally, ensure any forked or derivative code is patched to incorporate the new fixes.

Affected version: <=2.20.2

Resolution:

The patches are included in Amplify Studio `aws-amplify/amplify-codegen-ui` version 2.20.3. We recommend upgrading to the latest version and ensuring any forked or derivative code is patched to incorporate the new fixes.
